Methods

Participants. Our sample included 131 participants (mean age = 39.68 years, SD = 11.60, range 18–59; 51 males (38.93%), 37 females (28.24%) and 43 who reported another gender (32.82%)). 91 participants (69.47%) met the criteria for major depression (see Figure 1A). IQ scores were within the normal range (mean = 98.40, SD = 14.40, range 61.69–139.46; see Figure 1B). Sleep duration was also within the expected range (mean = 6.75 hours per night, SD = 1.58, range 3.11–9.80), with a similar distribution across gender groups (see Figure 1C).

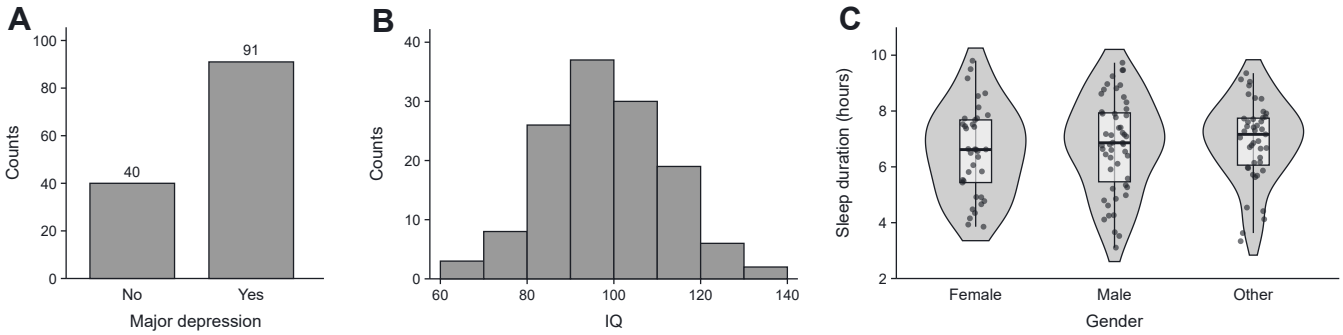

Figure 1. Sample characteristics. (A) Number of participants with and without major depression. (B) Histogram of IQ scores across the sample. (C) Sleep duration (hours per night) as a function of gender: boxplots, violin plots and individual participants. Most of the sample met the criteria for major depression, while IQ and sleep duration were within the expected range for the general population.
